Introduction of Product

Development of D85MS-15 Demining Dozer

Toshio Ibuki
Shigeru Yamamoto
Atsushi Nagira
Hiroshi Nakagami

More than one hundred million landmines are reported buried all over the world. The buried landmines are injuring many civilians and deminers every year. In August 2002, the antipersonnel demining dozer was removed from the list of military vehicles. In 2003, KOMATSU started the development of antipersonnel demining dozer for humanitarian aid with support provided by the Japanese government. The base machine was designated D85EX-15 and the machine was named “Model D85MS-15.” The most important functions for the demining dozer are working speed, demining accuracy and durability. D85MS-15 has achieved all these functional requirements as reported in the following.

Key Words: Demining dozer, D85MS-15, Afghanistan, Cambodia, humanitarian aid

1. Introduction

Aimed at supporting humanitarian aid, this development was conducted and subsidized by the Ministry of Economy, Trade and Industry and the New Energy and Industrial Technology Development Organization (NEDO). Afghanistan was selected as a target country for the initial stage of development. The country had decided the areas in which mines should be removed preferentially. Farmlands, pastures and roads account for 95% of the total area. The equipment was developed designed to remove mines in these land segments.

As the base machine, the D85EX-15 with a machine body weight of 27 tons was selected and the machine used the technology of the CS210 stabilizer as a high-efficiency mine processing device.

The machine is installed with a dedicated transmission, excavation control, shellproof device, radio control device for remote operation and a basket device for the recovery of mine fragments. It is no exaggeration to say that the demining dozer brings together the technologies of all the development centers of Komatsu. The details of the development are reported in the following (Photo 1).

Photo 1 General view of D85MS-15
2. **Aim of Development**

1. **Analysis of current situation**

   Afghanistan is a landlocked country surrounded by six countries. The southern part of the country is deserts, while the eastern, central and northern parts are mountainous areas.

   About 75% of the land area of the country totaling 652,000 km$^2$ (about 1.7 times the land area of Japan) is mountainous areas.

   The land described above was classified by area and targets were narrowed down (Fig. 1).

2007 ① VOL. 53 NO.159 Development of D85MS-15 Demining Dozer
3. Accomplishment Means

3.1 Working Capacity

(1) Selection of base machine
Taking into consideration the work on uneven ground and at a steep grade among the requirements mentioned on the previous page and in accordance with Komatsu’s policy “What is important for Japan is to build a demining system rather than competing among enterprises,” a unique bulldozer of Komatsu that was not manufactured by other companies was selected as the base machine.

In the selection of a machine type, a processing capacity about 20 times that of human capability was set as a goal. The processing capacity by human labor would be about 20 m$^2$ per hour or 400 m$^2$ by simple calculation.

Because a device developed in advance for the stabilizer (road repair machine) will be used in the mine processing device (rotor), the rotor will require a machine type that can run inside the processing width and power to rotate and process the rotor will be required. As the model that satisfies both of these requirements, the D85EX-15 was selected (Photo 2).

(2) Low-speed transmission
During normal work on an ordinary bulldozer, the gear is changed by:
- The gear shift is fixed and an optimum speed is maintained by controlling the blade, or
- The gear is shifted down automatically when the load is high using the auto shift down function and the maximum speed is maintained by controlling the blade when the load is high.

In both cases, the load is controlled ultimately by lifting or lowering the blade (Fig. 2).

Fig. 2 Control of normal bulldozer

The demining dozer can only retract to demined land and cannot change its cutting depth. For these reasons, an ultra-low-speed transmission had to be developed.

The F1 travel speed (demining gear shift) was set at 0.4 km/h based on an empirical value of 0.1 to 0.5 km/h for the rotor width of 2550 mm (stabilizer) and the goal of 400 m$^2$/h, which was more than 20 times the human capability.

Bases for calculation
- The working capacity was set at 500 m$^2$/h providing an allowance to the goal of 400 m$^2$/h or more.
- The efficiency was set at 50% as the demining dozer had to always retract after demining.

Demining area: 500 m$^2$/h ÷ 50% = 1000 m$^2$/h

Vehicle speed (km/h) = \frac{\text{Demining area per hour} \times \text{1000 m}^2/\text{h}}{\text{Rotor width 2.55 m}}

(3) Excavation control
Depending on soil type, soil cannot be dug by the demining rotor even by a low-speed transmission. A reliable demining method for a demining depth of 30 cm was accomplished by automatically controlling the transmission and rotor.

1) System configuration
The control system configuration is illustrated in Fig. 3. Each ECU is connected by CAN through which information and commands are transmitted.

![D85MS-15 Control System](image1)

**Fig. 3** Control system configuration

2) Gear shift control
The excavating depth of the demining dozer is predetermined and the vehicle has to be stopped if excavating is not possible (Fig. 4).

![Demining dozer controls vehicle speed](image2)

**Fig. 4** Control of demining dozer

Neutral control condition
Mines are removed reliably through the control specified in Table 3.

<table>
<thead>
<tr>

<td>Transmission neutral, brake ON</td>
</tr>
<tr>
<td>250 rpm or more</td>
<td>Forward 1st gear (F1) restart</td>
</tr>
</tbody>
</table>

Table 3 Neutral control

3) Load control
If rotations do not recover by the foregoing control, the operator has to lift and lower the rotor to remove the load. Rotor load control is adopted to further enhance demining work and to ease operator operability. Switching on the switch installed on the rotor lever starts load control (Photo 3).

![Load control switch](image3)

**Photo 3** Load control switch
Load control condition

Angle sensors installed on the rotor lift cylinders (Fig. 5) determine the rotor position and a mine is removed reliably through the control specified in Table 4.

<tr>
<td>50 to less than 250 rpm</td>
<td>Rotor position maintained</td>
</tr>
<tr>
<td>250 rpm or more</td>
<td>Rotor lowered</td>
</tr>
<tr>
<td>Rotor lowering completed</td>
<td>In 1 second, forward 1st gear (F1) restart</td>
</tr>
</tbody>
</table>

(4) Wide-width crushing device
The rotor was modified to enhance the working capacity and the excavating efficiency could be improved by about 50%.

Rotor modification

1) Fewer rotor bits (Fig. 6)

The excavating resistance varies in proportion to the number of bits. The number of bits was reduced from 206 to 142, thereby improving the excavating resistance by 31%. The reduction in the number of bits penetrating into the ground per second is compensated by increasing the rotor rotation speed through a reduction in the excavating resistance.

Actual conditions
1) 10 bit rows on rotor rim, pitch 25
2) 206 bit holders

Modification:
1) 6 bit rows on rotor rim, pitch 35
2) 142 bit holders

Fig. 5  Rotor position sensors (Mounted on left and right of vehicle)

Fig. 6 Fewer bits

Reduction ratio of excavating resistance (Comparison in number of bits)
100 - (142/206) x 100 = 31% reduction
2) Rotor bit arrangement changed from Type A to Type M (Fig. 7)

In demining work, it is dangerous to unload soil to the outside of the rotor width after demining and the bit arrangement of Type A has been adopted in the past. Soil that is ejected after demining is heaped in the center of the rotor, acting as a resistance to excavating. After demining, Type M bit arrangement was adopted and evenly ejected soil inside the rotor width, thereby reducing the excavating resistance.

3) Test results

• Test of work amount at excavating depth of 30 cm (Table 5)

<table>
<thead>
<tr>
<th>Soil</th>
<th>Unit</th>
<th>Work rate</th>
<th>Ratio</th>
</tr>
</thead>

</tr>
</tbody>
</table>

Result: 65% improvement recorded

• Destruction test

Destruction of dummy mines classified by excavating depth was checked (Photo 4).

3.2 Safety

(1) Shellproof device

The D85MS-15 can be operated both by an operator on the vehicle and by radio control. A shellproof-specification cab was developed to protect the operator on the vehicle and shellproof covers were installed to protect the vehicle in case of mine explosion near the vehicle.

1) Cab (Photo 8)

• All exteriors are lined with high tensile strength steel

Fig. 8 Shellproof cab
• All window glass panes adopt shellproof glass (Wreck Guard RS-1250).
Front windows, door windows, side windows:
\[ t_{33} + t_{20} = t_{53} \]
Rear windows: \( t_{20} \)

(2) Protection of vehicle body
• The engine side covers are closed side covers made of high tensile strength steel (Fig. 9).
• Covers made of high tensile strength steel have been added to fuel and hydraulic oil tanks (Fig. 10).

(2) Radio control device
Remote operation by radio control has been made possible to ensure safe mine removal work. This has been accomplished by turning all equipment to electronic equipment and by transmitting commands from the radio control system to the controller to drive each equipment as shown in the system configuration diagram.

• Electronic work equipment control (Fig. 11)

• Electronic brake control (Fig. 12)
(3) Front guard device
Stones, rocks, mine fragments and other debris dug during demining may eject in front of the rotor.
Safety of the demining dozer has been enhanced by capturing and reprocessing unexploded mine/s that bounce out during demining, even though this is not expected to occur.

- Basket type suitable for wide, dry land (Fig. 13)

![Basket type](image1)

- Chain type suitable for narrow, wet land (Fig. 14)

![Chain type](image2)

3.3 Other
(1) Rotor-free valve
The tip of each rotor claw is installed with a bit to destroy a mine (Photo 5). Bits are expendable parts and need to be replaced. A free valve (Fig. 15) connects Ports A and B of the motor to free rotor rotations. This makes bit replacement work easy.

![Rotor-free valve](image3)
(2) Demining dozer for infrastructure works

After demining work, the demining dozer can be used in infrastructure development works as an ordinary bulldozer by changing its attachments (Fig. 16).

4. Anti-explosion Test

4.1 Result of Test in Japan

1) Test at Shimokita Test Site, Technical Research and Development Institute, Ministry of Defense
   • Stationary test (no running) simulating the following three conditions (Fig. 17).
   • Test under 750g of C4 gunpowder (equivalent to largest personnel mine)

2) Test results
   • Shoe bolts sheared, one shoe plate fallen (Photo 6)
   • Tip of one bit chipped, 2 bits fallen (Photo 7)
   • Hydraulic pressure generated in hydraulic cylinder of work equipment: Max. 188 kg/cm²
   • Internal pressure generated inside operator’s cab: Max. 175 mmAq

Fig. 16 Conversion to bulldozer

Fig. 17 Locations of gunpowder

4.2 Results of Tests in Afghanistan and Cambodia
   Field verification tests were conducted in Afghanistan in 2004 and in Cambodia in 2006. In the tests, the actual work rate in the two countries exceeded 500 m$^2$/h. The demining dozer proved viable also on a steep inclined surface of about 30° in Afghanistan which abounds with mountains and hills (Photo 8) and in a shrub area in Cambodia (Photo 9).

5. Conclusion
   Several hundred million mines are mined throughout the world. Removal of these mines is an indispensable element to the development of the countries in which mines are placed.
   The performance of the demining dozer will definitely be able to make a contribution to demining activities, as well as to social infrastructure development and maintenance.

[A few words from the writers]
Motivated by an official invitation to participate in a Government project in 2003, only a short time was allowed for the development work. The series of work during this short period of time included anti-explosion tests at a Self-Defense Forces test site, discussions with Government officials and interviews by newspapers and TV stations. These experiences can be used in future work also.

Being a humanitarian aid project, warm cooperation was extended by personnel in the various related fields and a No. 2 machine could be built. The writers would like to thank those who provided their cooperation in this project.
